

CO150 - Recurrence Relations Cribsheet

Prelude

The content discussed here is part of CO150 - Graphs and Algorithms (Computing MEng); taught by Iain Phillips, in Imperial College London during the academic year 2018/19. Raihaan wanted me to do these. Probably copied mostly from the notes.

We refer to functions $W : \mathbb{N} \rightarrow \mathbb{N}$, and $A : \mathbb{N} \rightarrow \mathbb{N}$, as complexity functions. These will normally be solved by repeated expansion.

Binary Search

$$\begin{aligned} W(1) &= 1 \\ W(n) &= 1 + W(\lfloor \frac{n}{2} \rfloor) \\ &= 1 + 1 + W(\lfloor \frac{n}{4} \rfloor) \\ &\dots \\ &= 1 + 1 + \dots + 1 + W(1) \\ &= 1 + \lfloor \log_2(n) \rfloor \end{aligned}$$

The number of 1s we get is determined by how many times we can divide n by 2. Allow us to bound n as $2^k \leq n < 2^{k+1} \Leftrightarrow k \leq \log_2(n) < k+1$, hence $k = \lfloor \log_2(n) \rfloor$, and since $W(1) = 1$, $W(n) = 1 + \lfloor \log_2(n) \rfloor$.

Strassen's Algorithm

$$\begin{aligned} A(0) &= 1 \\ A(k) &= 7A(k-1) + 18\left(\frac{n}{2}\right)^2 \\ &= 7(7A(k-2) + 18\left(\frac{n}{4}\right)^2) + 18\left(\frac{n}{2}\right)^2 \\ &= 7^k + 18\frac{n^2}{4} \sum_{i=0}^{k-1} \left(\frac{7}{4}\right)^i \\ &= 7^k + 18\frac{n^2}{4} \cdot \frac{\left(\frac{7}{4}\right)^k - 1}{\frac{7}{4} - 1} \\ &= 7^k + 6n^2\left(\left(\frac{7}{4}\right)^k - 1\right) \\ &= 7^k + 6 \cdot 4^k \left(\left(\frac{7}{4}\right)^k - 1\right) \\ &= (1+6)7^k - 6 \cdot 4^k \\ &= 7 \cdot 7^k - 6 \cdot n^2 \\ &= 7n^{\log_2(n)} - 6 \cdot n^2 \end{aligned}$$

For this, we're assuming $n = 2^k$, so we can easily subdivide the matrix. If this isn't the case, we can easily pad the matrices with 0 rows, or columns. The standard result for the partial sum of a geometric series is applied here.

Merge Sort

$$\begin{aligned}W(1) &= 0 \\W(n) &= n - 1 + W(\lceil \frac{n}{2} \rceil) + W(\lfloor \frac{n}{2} \rfloor) \\&= n - 1 + 2W(\frac{n}{2}) \\&= n - 1 + 2(\frac{n}{2} - 1) + 2^2W(\frac{n}{2^2}) \\&= n + n - (1 + 2) + 2^2W(\frac{n}{2^2}) \\&\dots \\&= n + n + \dots + n - (1 + 2 + 2^2 + \dots + 2^{k-1}) + 2^k W(\frac{n}{2^k}) \\&= kn - (2^k - 1) + 0 \\&= n \log_2(n) - (n - 1) \\&= n \log_2(n) - n + 1 \\&= n \lceil \log_2(n) \rceil - 2^{\lceil \log_2(n) \rceil} + 1\end{aligned}$$

Note that here we're assuming $n = 2^k$, as it makes it easier. The standard result for a partial sum of a geometric series is used in the penultimate lines, and we take the ceiling, in order to generalise it for all n .

Master Theorem

Not really a recurrence relation, but it fits here.

Given the general form of a divide, and conquer algorithm; $T(n) = aT(\frac{n}{b}) + f(n)$, and critical exponent $E = \log_b(a)$

- if $n^{E+\epsilon} = O(f(n))$ for some $\epsilon > 0$, then $T(n) = \Theta(f(n))$
informally; if $O(n^E) < O(f(n)) \Rightarrow T(n) = \Theta(f(n))$
- if $f(n) = \Theta(n^E)$ then $T(n) = \Theta(f(n)\log(n))$
informally; if $O(n^E) = O(f(n)) \Rightarrow T(n) = \Theta(f(n)\log(n))$
- if $f(n) = O(n^{E-\epsilon})$ for some $\epsilon > 0$ then $T(n) = \Theta(n^E)$
informally; if $O(n^E) < O(f(n)) \Rightarrow T(n) = \Theta(n^E)$

Quicksort

Worst Case

$$\begin{aligned}W(1) &= 0 \\W(n) &= n - 1 + W(n - 1) \\&= \sum_{i=0}^{n-1} i \\&= \frac{n(n-1)}{2}\end{aligned}$$

This is no better than the worst case for insertion sort. However, it's fairly rare for this to happen, so we consider the average case.

Average Case

$$A(0) = 0$$

$$A(1) = 0$$

$$\begin{aligned} A(n) &= n - 1 + \frac{1}{n} \sum_{s=0}^{n-1} (A(s) + A(n - s - 1)) \\ &= n - 1 + \frac{2}{n} \sum_{i=2}^{n-1} A(i) \end{aligned}$$

This can then be used to prove $A(n)$ is $\Theta(n \log(n))$, but I'm not going to do that, because it's tedious.

Word Split Problem

$$W_1(0) = 0$$

$$\begin{aligned} W_1(n) &= n + \sum_{i=0}^{n-1} W_1(i) \\ &= n + W_1(n - 1) - (n - 1) + W_1(n - 1) \\ &= 1 + 2W_1(n - 1) \\ &= 2^n - 1 \end{aligned}$$

Note that the second line of the recurrence relation is justified by observing how all the terms from 0 to $n - 2$ are already present in $W_1(n - 1)$. Not in the notes, just something I wanted to check.

Suppose $W_1(n - 1) = n - 1 + \sum_{i=1}^{n-2} W_1(i)$. By arithmetic, it follows that $\sum_{i=1}^{n-2} W_1(i) = W_1(n - 1) - n + 1$.

$$\begin{aligned} W_1(n) &= n + \sum_{i=0}^{n-1} W_1(i) \\ &= n + \sum_{i=0}^{n-2} W_1(i) + W_1(n - 1) && \text{by def. of } \Sigma \\ &= n + W_1(n - 1) - n + 1 + W_1(n - 1) && \text{by substitution} \\ &= 1 + 2W_1(n - 1) && \text{by arithmetic} \end{aligned}$$
