CO142 - Discrete Structures

9th October 2018

Recommended Books

- K.H. Rosen. Discrete Mathematics and its Applications
- J.L. Gersting. Mathematical Structures for Computer Science
- J.K. Truss. Discrete Mathematics for Computer Science
- R. Johsonbaugh. Discrete Mathematics
- C. Schumacher. Fundamental Notions of Abstract Mathematics

However, these books don't cover the same content. Learn his notation.

Logical Formula, and Notation

This notation will be shared with CO140.

$A \wedge B$	A and B both hold
$A \vee B$	$A ext{ or } B ext{ holds (or both)}$
$\neg A$	A does not hold
$A \Rightarrow B$	if A holds, then so does B
$A \Leftrightarrow B$	A holds if and only if B holds
$\forall x(A)$	the predicate A holds for all x
$\exists x(A)$	the predicate A holds for some x
$a \in A$	the object a is in the set A (a is an element of A)
$a \notin A$	the object a is not in the set A
$=_A$	tests whether two elements of A are the same

Sets

Sets are like data types in Haskell: Haskell data type declaration;

A set is a collection of objects from a pool of objects. Each object is an *element*, or a *member* of the set. A set *contains* its elements. Sets can be defined in the following ways;

```
\{a_1, ..., a_2\} as a collection of n distinct elements \{x \in A \mid P(x)\} for all the elements in A, where P holds \{x \mid P(x)\} for all elements, where P holds (dangerous - Russel's paradox)
```

Use of "triangleq"

The use of \triangleq is for "is defined by". Hence the empty set, $\varnothing \triangleq \{\}$. The difference between \triangleq and =, is that the former cannot be proven, it is fact, whereas the latter takes work to prove.

Russel's paradox

Not everything we write as $\{x \mid P(x)\}$ is automatically a set. Assume $R = \{X \mid X \notin X\}$ is a set, the set of all sets which don't contain themselves. As R is a set, then $R \in R$, or $R \notin R$ (law of excluded middle), and thus we can do a case by case analysis.

- Assume $R \in R$. By the definition of R, it then follows that $R \notin R$ (if $R \in R$, then it doesn't satisfy the definition of R) which is a contradiction.
- Assume $R \notin R$. It then follows that $R \in R$, as it follows the definition of R, hence it is another contradiction.

As both assumptions lead to contradictions, it's possible to write sets which aren't defined. We should only select from a set that we know is defined; $\{x \in A \mid P(x)\}\$ - where A is a well-defined set.
